Introduction to Decision making Types of decision making statements

- if statement
- if...else statement
- nested if statement
- elif statement

Decision making is a significant perspective in any programming language. It assists with taking an alternate way in the code dependent on the dynamic outcomes. This helps a great deal in process automation kind of stuff, where sooner or later in the process there could be numerous different ways, and the state by then chooses the way to be taken.

Decision structures evaluate multiple expressions which produce TRUE or FALSE as outcome. You need to determine which action to take and which statements to execute if outcome is TRUE or FALSE otherwise.

Python programming language provides following types of decision making statements.

- if Statements
- if...else statements
- nested if statements

1) if statement:

An **if** statement consists of a Boolean expression followed by one or more statements.

A Boolean expression is evaluated and if TRUE, a block of statements are executed else, the execution flow continues with the execution of statements after if statement.

1) if statement:

The syntax of if statement is:

if expression:
 statement(s)

If the **expression** is evaluated to TRUE, the statement gets executed. But if it's FALSE, nothing happens.

1) if statement:

Example:

```
a = 15
if (a > 10): #you can also write as if a>10:
  print("a is greater")
```

2) If...else Statement:

An **if** statement can be followed by an optional **else** statement, which executes when the Boolean expression is **false**.

A Boolean expression is evaluated and if TRUE, a block of statements are executed else another block of statements are executed, then the execution flow continues with the execution of statements after if statement.

2) If...else Statement:

```
The syntax of if...else statement is:
if expression:
    statement(s)
else:
    statement(s)
```

The else part is optional and is only evaluated if **expression** is evaluated to be FALSE.

2) If...else Statement:

Example:

```
x = 305
y = 405
if x > y:
    print("x is greater")
else:
    print("y is greater")
```

3) Nested if statements:

A **nested if** is an **if statement** that is the target of another if statement. Nested if statements means an **if statement** inside another **if statement**. Yes, Python allows us to nest if statements within if statements. i.e., we can place an **if statement** inside another **if statement**.

3) Nested if statements:

```
The syntax of nested if statement is if expression:
    if expression:
        statement(s)
    else:
        statement(s)
else:
    statement(s)
```

3) Nested if statements:

```
Example:
a = 56
if(a > 40):
  if(a > 45):
     print("a is greater than 45")
  else:
     print("a is less than 45")
else:
  print("a is less than 40")
```

elif statement:

The **elif** statement allows you to check multiple expressions for TRUE and execute a block of code as soon as one of the conditions evaluates to TRUE. Similar to the **else**, the **elif** statement is optional. However, unlike else, for which there can be at most one statement, there can be an arbitrary number of **elif** statements following an **if**. elif - is a keyword used in Python replacement of else if to place another condition in the program. This is called chained conditional.

```
The syntax of elif statement is:
if expression1:
 statement(s)
elif expression2:
 statement(s)
elif expression3:
 statement(s)
else:
 statement(s)
```

elif statement:

elif statement:

Example:

```
P = 15
Q = 15
if P > Q:
    print("P is greater")
elif P == Q:
    print("both are equal")
elif P < Q:
    print("Q is greater")</pre>
```
